Statistics with R - Exercise 1

Philipp Satlawa - h0640348

06/11/2020

This document contains the answered questions of exercise 1 for the course "Statistics with R".

Task 1 - Sequences

Creation and comparison of vectors.

1. Create a vector x that contains the sequence of even numbers from 0 to 40 ($x \in \mathbb{R}$)

```
(x \le seq(from = 0, to = 40, by = 2))
```

- **##** [1] 0 2 4 6 8 10 12 14 16 18 20 22 24 26 28 30 32 34 36 38 40
 - 2. Create a vector y, which contains the elements of vector x but in random order $(y \in x)$

```
# set seed to produce reproducible results
set.seed(10)
# take random samples from the elements of vector x
(y <- sample(x))</pre>
```

- **##** [1] 20 16 18 30 22 12 14 10 34 4 28 36 24 2 40 8 32 38 6 0 26
 - 3. The values of x and y agree on the following positions:

```
# number of positions the two vectors agree on
length(which(x == y))
```

[1] 2

```
# indices (positions) on which the values of the two vectors agree on which(x == y)
```

[1] 13 17

Task 2 - Sequences

Verification of three approximation formulas for π . Since the calculation of π by the following formulas includes infinite sums or products, we use a large n = 10000.

Creating vector \mathbf{i} as a sequence from 1 to 100000 ($\mathbf{x} \in \mathbb{R}$).

```
# create vector i
i <- 1:10000

1. John Wallis (1616-1703):
# calculation of pi with the formula of John Wallis
prod((2*i/(2*i-1)) * (2*i/(2*i+1)))*2

## [1] 3.141514

2. Gottfried Leibnitz (1646-1716):
# calculation of pi with the formula of Gottfried Leibnitz
sum(((-1)**(i+1))/(2*i-1))*4

## [1] 3.141493

3. Leonhard Euler (1707-1783):
# calculation of pi with the formula of Leonhard Euler
sqrt(sum(1/i**2)*6)</pre>
```

[1] 3.141497

[1] 1e-04

To compute the smallest relative deviation from π given the vector \mathbf{i} , we need π 's current best approximation. Acording to ikipedia (2020) pi's current best approximation is 3.1415926535897932384626433.

```
# store pi's current best approximation for comparison
pi <- 3.1415926535897932384626433

# calculate the difference between John Wallis (1616-1703) and current pi
(diff_JW <- abs(prod((2*i/(2*i-1)) * (2*i/(2*i+1)))*2 - pi))

## [1] 7.853491e-05

# calculate the difference between Gottfried Leibnitz (1646-1716) and current pi
(diff_GL <- abs(sum(((-1)**(i+1))/(2*i-1))*4 - pi))</pre>
```

```
# calculate the difference between Leonhard Euler (1707-1783) and current pi
(diff_LE <- abs(sqrt(sum(1/i**2)*6) - pi))
## [1] 9.548964e-05
# get the absolute difference of the formula with the smallest absolute difference
min(diff_JW, diff_GL, diff_LE)</pre>
```

[1] 7.853491e-05

Hance, the approximation formula for π with the smallest relative deviation for n=10000 is John Wallis (1616-1703) formula.

Task 3 - Vectors

Creation and manipulation of vectors.

1. Create vector \mathbf{x} containing the sequence 1 to 100 ($\mathbf{x} \in \mathbb{R}$) and vector 'y' containing a sample of size $\mathbf{n} = 70$ of the sequence 1 to 150 ('y' $\in \mathbb{R}$).

```
# create vector x containing the sequence 1 to 100 (natural numbers)
(x \leftarrow 1:100)
     [1]
                                                                                     18
##
           1
                2
                    3
                         4
                             5
                                 6
                                      7
                                          8
                                               9
                                                  10
                                                      11
                                                           12
                                                               13
                                                                   14
                                                                        15
                                                                            16
                                                                                 17

## [22] 0.6294263 3.6502681 0.7618776 2.4696040 4.2526769 3.6248891 3.2556823
## [29] 4.7964780 4.4924389
2. Estimate \mu and \sigma^2 on the basis of your sample using the formulas to estimate the population mean \mu
with the sample mean \bar{x} and the population variance \sigma^2 with the empirical variance s^2, without using the
functions mean(), var() and sd().
# calculation of mean
(sum(x)/length(x))
## [1] 4.310647
# calculation of variance
(1/(length(x)-1) * sum((x-mean(x))**2))
## [1] 3.00578
# calculation of standard deviation
(\operatorname{sqrt}(1/(\operatorname{length}(x)-1) * \operatorname{sum}((x-\operatorname{mean}(x))**2)))
## [1] 1.733718
  3. Compare your results with the output of the functions mean() and var().
# compute the mean with inbuilt function mean()
(mean(x))
## [1] 4.310647
# check if the results of the inbuilt function mean() and the formula for calculating the mean are the
if(round(sum(x)/length(x),5) == round(mean(x),5)) {
  ("same")
} else {
  ("diffrent")
## [1] "same"
# compute the variance with inbuilt function var()
(var(x))
## [1] 3.00578
```

```
# check if the results of the inbuilt function var() and the formula for calculating the variance are t
if(round((1/(length(x)-1) * sum((x-mean(x))**2)),5) == round(var(x),5)) {
  ("same")
} else {
  ("diffrent")
## [1] "same"
# compute the standard variation with inbuilt function sd()
(sd(x))
## [1] 1.733718
# check if the results of the inbuilt function sd() and the formula for calculating the variance are th
if(round(sqrt(1/(length(x)-1) * sum((x-mean(x))**2)),5) == round(sd(x),5))  {
  ("same")
} else {
  ("diffrent")
## [1] "same"
  4. Are your estimates close to the population values? Repeat the steps 1 and 3 from above with a sample
     of size n = 3000. What do we learn?
# set seed to produce reproducible results
# draw random sample with n = 3000, mu = 5, sigma^2 = 4
x \leftarrow rnorm(3000, mean = 5, sd = sqrt(4))
# calculation of mean
(sum(x)/length(x))
## [1] 5.002634
# calculation of variance
(1/(length(x)-1) * sum((x-mean(x))**2))
## [1] 4.143197
# calculation of standard deviation
(\operatorname{sqrt}(1/(\operatorname{length}(x)-1) * \operatorname{sum}((x-\operatorname{mean}(x))**2)))
## [1] 2.035484
# compute the mean with inbuilt function mean()
(mean(x))
## [1] 5.002634
```

```
# check if the results of the inbuilt function mean() and the formula for calculating the mean are the
if(round(sum(x)/length(x),5) == round(mean(x),5)) {
  ("same")
} else {
  ("diffrent")
## [1] "same"
# compute the variance with inbuilt function var()
(var(x))
## [1] 4.143197
# check if the results of the inbuilt function var() and the formula for calculating the variance are t
if(round((1/(length(x)-1) * sum((x-mean(x))**2)),5) == round(var(x),5))  {
  ("same")
} else {
  ("diffrent")
## [1] "same"
# compute the standard variation with inbuilt function sd()
(sd(x))
## [1] 2.035484
# check if the results of the inbuilt function sd() and the formula for calculating the variance are th
if(round(sqrt(1/(length(x)-1) * sum((x-mean(x))**2)),5) == round(sd(x),5))  {
  ("same")
} else {
  ("diffrent")
## [1] "same"
```

The conclusion of the above calculations shows, the higher the sample size n the smaller is the deviation between the sample mean \bar{x} and the population mean μ . The same applies for the variance and standard deviation.

Task 5 - Interval Estimation

Calculate the confidence intervals for the mean and the variance.

1. Draw a reproducible sample of size n=30 from a normal distribution with $\mu=5$ and $\sigma^2=4$.

```
# set seed to produce reproducible results
set.seed(10)
# draw random sample
(x \leftarrow rnorm(30, mean = 5, sd = sqrt(4)))
## [1] 5.0374923 4.6314949 2.2573389 3.8016646 5.5890903 5.7795886 2.5838476
## [8] 4.2726480 1.7466546 4.4870432 7.2035590 6.5115630 4.5235329 6.9748894
## [15] 6.4827803 5.1786945 3.0901123 4.6096992 6.8510425 5.9659570 3.8073787
## [22] 0.6294263 3.6502681 0.7618776 2.4696040 4.2526769 3.6248891 3.2556823
## [29] 4.7964780 4.4924389
  2. Calculate a confidence interval for \mu and \sigma^2 for \alpha = 0.05 (hence the confidence level is 1 - \alpha 1 = 0.95).
     Inbuilt functions such as mean(), sd() and var() are allowed. looked up in sktiptum t(29;0.975) = 2.045
# looked up the t-value in the skript t(29;0.975) = 2.045
# qet t-value for n-1 = 29; 1-alpha = 0.975 from an inbuilt R function
(t \leftarrow qt(0.975, df=29))
## [1] 2.04523
# lower bound mean
(low_bound_mean \leftarrow mean(x) - t * sd(x)/sqrt(length(x)))
## [1] 3.663266
# upper bound mean
(up\_bound\_mean \leftarrow mean(x) + t * sd(x)/sqrt(length(x)))
## [1] 4.958028
# get chi-value for n-1 = 29; 1-alpha = 0.975
(qchisq(0.975, df=29))
## [1] 45.72229
# lower bound standard dev
(low_bound_var \leftarrow ((length(x)-1) * var(x)) / qchisq(0.975, df=29))
## [1] 1.906458
# upper bound standard dev
(up\_bound\_var \leftarrow ((length(x)-1) * var(x)) / qchisq(0.025, df=29))
## [1] 5.431995
```

3. Determine if true parameters lie in the confidence interval.

```
# check if the mean lies within the confidence interval of the mean
if((mean(x) > low_bound_mean) & (mean(x) < up_bound_mean)){
   ("the mean lies within the confidence interval")
} else{
   ("the mean lies outside the confidence interval")
}</pre>
```

[1] "the mean lies within the confidence interval"

```
# check if the variance lies within the confidence interval of the variance
if((var(x) > low_bound_var) & (var(x) < up_bound_var)){
    ("the variation lies within the confidence interval")
} else{
    ("the variation lies outside the confidence interval")
}</pre>
```

[1] "the variation lies within the confidence interval"

Yes, in our case the true parameters lie within our confidence intervals. This is true for both the mean and the variance. The mean and the variance are in within the confidence intervals with a 5% probability of error.
